[Practice]

When you are ready, let's begin this practice. Today we will execute a Sound Mapping Exercise. To use the concept of spatial orientation, we will process our environment as data. We will treat sounds as specific information that defines our physical location.

We will use these sounds to build a mental map of the room, ensuring our tracking remains accurate and focused.

Before we start the scan, set your physical baseline. Sit or stand with a straight spine to support high-level monitoring. If you can, close your eyes. This forces your mind to block out visual distractions and rely only on sound to calculate your position.

[Short Pause] (10s - Starting Coordinates)

As you proceed, maintain a strict analytical focus. Your goal is to identify each sound as a separate piece of information. Set your current position as the center point.

Visualize a straight line running left to right and another running front to back. This is your coordinate system. Take a normal breath to mark your baseline and prepare for data collection.

Identify distinct sound sources. Classify them as separate items. If the room is very quiet, look for tiny sounds. Listen for the hum of a vent, the sound of a clock, or the settling of the building structure.

These are all valid data points for this survey. Identify Source A. Is it a machine, a person, or the environment? Next, find Source B.

Do not think about whether you like the sound or how it makes you feel. Simply record where it comes from and what generated it. Build a mental list of at least three distinct sounds. Verify each one before moving on.

[Long Pause] (25s - Identifying Sources)

Now, organize the data. Select one specific sound and analyze its properties. Is the pitch high or low? Is the sound constant, or does it start and stop? Give this sound a clear label.

For example: "Source A is low-frequency, constant, and steady." Verify that this label is correct. Continue to monitor the signal. Does the volume change? If the sound changes, update your mental record immediately to keep the data accurate.

[Long Pause] (30s - Quality Analysis)

Shift your focus to Spatial Mapping. Calculate where these sounds are located compared to your center point. Select the clearest signal and estimate its distance and trajectory.

How many meters away is the source? Is it within one meter, across the room, or outside the building? Draw a mental line from your position to the sound.

Pinpoint its exact spot on your mental map. If there are no clear sounds, map the distance to the four architectural walls of the room instead.

Calculate the distance to the wall in front of you and the wall behind you to complete the room's dimensions.

[Long Pause] (30s - Distance Calculation)

Now, test your ability to isolate a signal. Select one specific target sound. Treat all other sounds as "static" or background interference. Your task is to filter your hearing until only that one sound remains.

Actively block out the interference. If the room is nearly silent, use the faintest hum as your target. Focus strictly on tracking that one steady sound for several seconds.

[Short Pause] (10s - Signal Filter)

Maintain the integrity of your map by performing a cross-reference of the data. Compare Source A and Source B to see if their volumes are matched.

Determine if one sound blocks your ability to track the other. Check if the distance between these sources remains fixed or if the acoustic pattern is changing. This update ensures that your record of the room remains current and accurate.

[Short Pause] (10s - Cross-Reference Audit)

With every calculation, your mental map should become clearer. You are learning your exact physical relation to the sounds around you. Continue scanning for new sounds and add them to your map immediately. Keep the map updated as new data enters the environment.

Now, perform a Volume Ranking. Rank your sounds by how loud they are. Identify the loudest and the quietest sources. Compare the difference between them.

Try to find the absolute quietest sound in the room. Map the very bottom layer of the sound in this space to find the foundational acoustic floor.

[Pause] (20s - Final integration)

Finally, conclude the auditory scan and return to the center point. Verify your position on the chair. You are the fixed starting point of this map.

Take a standard breath to mark the end of the data collection, and then open your eyes.

Thank you for your practice.
